

Memoirs of the Royal Astronomical Society Volume 53

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1899 Excerpt: ...coefficients of expansion of brass and glass is such that the plate once placed in the true focus will always remain so, however great be the temperature variations. It may be observed that it is of no importance to know the actual focal length of the lens, this quantity not being required in the formulae of reduction. Some form of sighting arrangement or finder must be provided, to enable the observer so to direct the camera that the centre of the field falls at any desired point in the sky. A pinhole and sight vane on arms attached to the top of the camera, which can be turned down when not in use, will be found to fulfil this purpose in a satisfactory manner. The exposing arrangement that seems preferable is a simple flap shutter, actuated by a pneumatic ball, with sufficient length of tubing to allow the observer to keep at a distance of about four feet from the camera, and thus enable it to realise the high degree of stability essential to success. That form which is sold by photographic dealers under the name of studio shutter is quite suitable, a particularly good pattern being that in which the exposing arrangement is a light blind which opens from, and closes to, the centre. The slight shock of the opening of the light flap or blind does not move a heavy camera to a measurable extent. The plate-holder should be of metal, and must be provided with some means by which the position of the sensitive plate in the slide can be readily determined, and with an adjustment which will cause the plate to take up a position truly perpendicular to the optical axis. This is completely effected by making the plate rest against three sharp pointed screws, which puncture the gelatine film and give

three points from which the position of the
