

## Popular astronomy Volume 10

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1902 Excerpt: ... this purpose, having but a small selective absorption for the white light which passes through it. This is not the case with a great many reflecting and refracting materials. Take, for instance, a highly polished silvered surface such as we find in the best mirrors. You would probably imagine that it reflects most of the light which falls upon it; but if you arrange two mirrors in such a way that a beam of white light containing all the colors of the spectrum, shall have twelve reflections, you will find the beam of light at the last reflection to be almost pure red, having been robbed of the violet, blue, and green waves. Many kinds of glass have the same properties. The dense Faraday glass will absorb nearly all the short waves after transmission through four or five inches of thickness. The boro-silicate crown is very white and transparent. It is also what we call a dry glass. Many of the crown glasses made have a great affinity for the moisture in the atmosphere, perhaps on account of the potash in them, and are called hygroscopic. They soon become dimmed over the surface, thus shutting out, as well as diffusing, much light. The polished surface of the borosilicate crown remains free from patina for years. I wish to say that the larger share in the development of this excellent field glass is due to The Warner & Swasey Company. They have studied it in every part, eliminating all superfluous attachments; made every part interchangeable; and, what is most important, have given to the two systems (*i. e.*, the two tubes with their optical parts) a most perfect alignment with one another, without which, even if all other things were made perfect, the instrument would not fulfill the function of a high-grade field

glass. I have been requested...
