

## The sidereal messenger Volume 10 ; a monthly review of astronomy

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1891 Excerpt: ...light frame of brass tubing sliding between V-shaped guides. After many experiments the steadiest motion that could be obtained was derived by a fine wire from the clock of the horizontal telescope, but this was very unsatisfactory, and the friction of the guides of the sliding-plate-holder made it impossible to obtain a perfectly smooth and uniform motion. In August, 1890, I planned a new form of sliding-plateholder, in which the friction was relieved by wheels running on knife edges, a simple change giving a stationary slit and moving plate, or a moving slit and a stationary plate. But this apparatus was never constructed, for a new idea occurred to me which was carried out in an apparatus made by Mr. Brashear. In the place of a sliding-plate-holder a rotating cylinder was substituted, and around this a strip of thin celluloid photographic film is wrapped, and held by a spring clips. The cylinder is held in a small brass box attached to the end of the observing telescope of the spectrocope, the axis of the cylinder passing through the top of the box, and carrying the pulley by which the cylinder is rotated. The bottom of the box is hinged, so that the cylinder can be removed in order to allow the second slit to be observed with a positive eye-piece passing through the back of the box. This slit can be opened or closed by turning a head at the side of the box, and by means of a slide passing before the slit the box can be closed and removed from the spectrocope without danger of exposing the film to the light. A means of producing a slow and uniform motion is the other requisite of the method, and a modified form of clepsydra is attached to the observing telescope for this purpose. A
