

Disulfide/Dithiol redox titrations of proteins: Regulation of protein expression

Redox-active disulfide/dithiol (D/D) couples in proteins play important regulatory roles within cells. D/D redox reactions of proteins found in the purple photosynthetic bacteria *R. sphaeroides* and *R. capsulatus* are used to regulate the expression of photosystem components in response to the presence oxygen and light. D/D redox reactions of regulatory proteins found in the yeast *S. cerevisiae* regulate the production of peroxide-scavenging proteins. AppA and PpsR are present in *R. sphaeroides* regulate gene expression in response to oxygen. It has been proposed that AppA reduces PpsR, causing PpsR to lose its ability to bind DNA. Redox titrations of the D/D couples in PpsR and AppA were carried out at pH 7.0 and the two proteins were shown to be isopotential, having E_m values of -320 mV. Yap1 is a key regulator of gene expression in *S. cerevisiae* in response to peroxides. Gpx3 and Trx2 are two additional components. E_m values for the two disulfide bonds in Yap1 have been determined ($E_{m1} = -330$ mV and $E_{m2} = -155$ mV), as has an E_m value of -315 mV for Gpx3. Trx2 has an E_m of -275 mV, which is capable of reducing the disulfide in Yap1 that corresponds to E_{m2} , but not E_{m1} .
